

Supplementary Document for “Submodularity Cuts and Applications”

In this supplementary material, we give the detail of a way to compute γ -extensions in Sect. A and an outline of the submodular maximization algorithm by Nemhauser and Wolsey [16] in Sect. B.

A Details of the computation of γ -extensions

Here, we describe a way to compute the γ -extensions of the directions $\mathbf{d}_1, \dots, \mathbf{d}_n$ chosen in Sect. 3.1 of our manuscript. Let S be a set with $|S| = k$, and let i^* and j^* are specified elements in S and $V \setminus S$, respectively, and suppose that $S = \{i_1, \dots, i_k\}$ with $i_1 = i^*$ and $V \setminus S = \{j_{k+1}, \dots, j_n\}$ with $j_n = j^*$. Remember that we chose the directions $\mathbf{d}_1, \dots, \mathbf{d}_n$ as

$$\mathbf{d}_l = \begin{cases} \mathbf{e}_{j^*} - \mathbf{e}_{i_l} & \text{if } l \in \{1, \dots, k\} \\ \mathbf{e}_{j_l} - \mathbf{e}_{j^*} & \text{if } l \in \{k+1, \dots, n-1\} \\ -\mathbf{e}_{j^*} & \text{if } l = n, \end{cases} \quad (8)$$

and gave the following lemma (Lemma 6 in Sect. 3.1):

Lemma 6 For the directions $\mathbf{d}_1, \dots, \mathbf{d}_n$ defined in Eqs. (8), a cone

$$K(\mathbf{I}_S; \mathbf{d}_1, \dots, \mathbf{d}_n) = \{\mathbf{I}_S + t_1 \mathbf{d}_1 + \dots + t_n \mathbf{d}_n : t_l \geq 0\}$$

contains the polytope $D_0 = \{\mathbf{x} \in \mathbb{R}^n : 0 \leq x_l \leq 1 \ (l = 1, \dots, n), \sum_{l=1}^n x_l \leq k\}$.

Proof Let $T \subset V$ be an arbitrary fixed set with $|T| \leq k$. We have that $T \in S(D_0)$ and $\mathbf{I}_T \in V(D_0)$. To show the assertion, it suffices to show $\mathbf{I}_T \in K(\mathbf{I}_S; \mathbf{d}_1, \dots, \mathbf{d}_n)$ because of the one-to-one correspondence between $S(D_0)$ and $V(D_0)$. Let us partition the set S into three parts $S_1 = \{i'_1, \dots, i'_{|S \cap T|}\}$, $S_2 = \{i'_{|S \cap T|+1}, \dots, i'_{|T|}\}$, and $S_3 = \{i'_{|T|+1}, \dots, i'_k\}$, where

$$S_1 = S \cap T \quad \text{and} \quad S_2 \cup S_3 = S \setminus T.$$

In addition, we partition the set T into two parts $T_1 = T \cap S = S_1$ and $T_2 = T \setminus S = \{j'_{|S \cap T|+1}, \dots, j'_{|T|}\}$. Then, we have

$$\begin{aligned} \mathbf{I}_T &= \mathbf{I}_S - \mathbf{I}_{S \setminus T} + \mathbf{I}_{T \setminus S} \\ &= \mathbf{I}_S + (\mathbf{I}_{T_2} - \mathbf{I}_{S_2}) - \mathbf{I}_{S_3} \\ &= \mathbf{I}_S + \sum_{l=|S \cap T|+1}^{|T|} (\mathbf{e}_{j'_l} - \mathbf{e}_{i'_l}) + \sum_{l=|T|+1}^k (-\mathbf{e}_{i'_l}) \\ &= \mathbf{I}_S + \sum_{l=|S \cap T|+1}^{|T|} \{(\mathbf{e}_{j'_l} - \mathbf{e}_{j^*}) + (\mathbf{e}_{j^*} - \mathbf{e}_{i'_l})\} + \sum_{l=|T|+1}^k \{(\mathbf{e}_{j^*} - \mathbf{e}_{i'_l}) + (-\mathbf{e}_{j^*})\}. \end{aligned}$$

Therefore, we obtain $\mathbf{I}_T \in \{\mathbf{I}_S + t_1 \mathbf{d}_1 + \dots + t_n \mathbf{d}_n : t_l \geq 0\}$. ■

Suppose that \mathbf{I}_S is a vertex of a polytope $P \subseteq D_0$ and γ is a constant number such that $f(S) \leq \gamma$ and $f(S_{(i,j)}) \leq \gamma$ for any neighbor $S_{(i,j)}$ of S . For the directions $\mathbf{d}_1, \dots, \mathbf{d}_n$ defined in Eqs. (8), the submodularity cuts algorithm requires the γ -extensions $\mathbf{y}_l = \mathbf{I}_S + \theta_l \mathbf{d}_l$ ($l = 1, \dots, n$) with respect to the Lovász extension $\hat{f} : \mathbb{R}^n \rightarrow \mathbb{R}$. To obtain these γ -extensions, it suffices to consider the following three cases.

- For $i \in S$ and $j^* \in V \setminus S$, compute a γ -extension $\mathbf{y}^{(1)} = \mathbf{I}_S + \theta^{(1)}(\mathbf{e}_{j^*} - \mathbf{e}_i)$.
- For two distinct $j, j^* \in V \setminus S$, compute a γ -extension $\mathbf{y}^{(2)} = \mathbf{I}_S + \theta^{(2)}(\mathbf{e}_j - \mathbf{e}_{j^*})$.
- For $j^* \in V \setminus S$, compute a γ -extension $\mathbf{y}^{(3)} = \mathbf{I}_S + \theta^{(3)}(-\mathbf{e}_{j^*})$.

Let us give explicit representations of $\theta^{(1)}$, $\theta^{(2)}$ and $\theta^{(3)}$.

A.1 Computation of $\theta^{(1)}$

We have $\theta^{(1)} = \max\{t \geq 0 : \hat{f}(\mathbf{y}(t)) \leq \gamma\}$, where $\mathbf{y}(t) := \mathbf{I}_S + t(\mathbf{e}_{j^*} - \mathbf{e}_i)$. Note that $f(S) = \hat{f}(\mathbf{y}(0)) \leq \gamma$ and $f(S_{(i,j^*)}) = \hat{f}(\mathbf{y}(1)) \leq \gamma$. The convexity of \hat{f} implies $\theta^{(1)} \geq 1$. Thus,

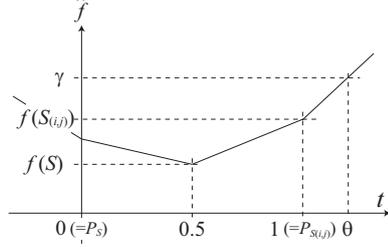

Figure 1: Determination of θ in computing the γ -extension through Lovász extension for $l \in \{1, \dots, k\}$ (cf. Eq. (8)).

we consider a parameter $t \geq 1$. The different components of $\mathbf{y}(t)$ are ordered as $t \geq 1 > 0 \geq 1 - t$, and $\mathbf{y}(t)$ can be represented as

$$\mathbf{y}(t) = (t - 1) \cdot \mathbf{I}_{\{j^*\}} + 1 \cdot \mathbf{I}_{S_{(i,j^*)}} + (t - 1) \cdot \mathbf{I}_{V \setminus \{i\}} + (1 - t) \cdot \mathbf{I}_V.$$

In view of the definition of the Lovász extension, the value of $\hat{f}(\mathbf{y}(t))$ is given by

$$\begin{aligned} \hat{f}(\mathbf{y}(t)) &= (t - 1) \cdot f(\{j^*\}) + 1 \cdot f(S_{(i,j^*)}) + (t - 1) \cdot f(V \setminus \{i\}) + (1 - t) \cdot f(V) \\ &= f(S_{(i,j^*)}) + (t - 1) \left\{ f(\{j^*\}) + f(V \setminus \{i\}) - f(V) \right\}. \end{aligned}$$

So, $\theta^{(1)}$ is bounded if and only if $\frac{d}{dt} \hat{f}(\mathbf{y}(t)) = f(\{j^*\}) + f(V \setminus \{i\}) - f(V) > 0$. As a result, we have the following (see also Fig. 1):

$$\theta^{(1)} = \begin{cases} 1 + \frac{\gamma - f(S_{(i,j^*)})}{f(\{j^*\}) + f(V \setminus \{i\}) - f(V)} & \text{if } f(\{j^*\}) + f(V \setminus \{i\}) - f(V) > 0, \\ +\infty & \text{otherwise.} \end{cases}$$

A.2 Computation of $\theta^{(2)}$

We have $\theta^{(2)} = \max\{t \geq 0 : \hat{f}(\mathbf{y}(t)) \leq \gamma\}$, where $\mathbf{y}(t) := \mathbf{I}_S + t(\mathbf{e}_j - \mathbf{e}_{j^*})$. Note that $f(S) = \hat{f}(\mathbf{y}(0)) \leq \gamma$. First, we suppose that $t \in [0, 1]$. The different components of $\mathbf{y}(t)$ are ordered as $1 \geq t > 0 \geq -t$ and $\mathbf{y}(t)$ can be represented as

$$\mathbf{y}(t) = (1 - t) \cdot \mathbf{I}_S + t \cdot \mathbf{I}_{S \cup \{j\}} + t \cdot \mathbf{I}_{V \setminus \{j^*\}} + (-t) \cdot \mathbf{I}_V.$$

Thus, the value of $\hat{f}(\mathbf{y}(t))$ is given by

$$\begin{aligned} \hat{f}(\mathbf{y}(t)) &= (1 - t) \cdot f(S) + t \cdot f(S \cup \{j\}) + t \cdot f(V \setminus \{j^*\}) + (-t) \cdot f(V) \\ &= f(S) + t \cdot \left\{ f(S \cup \{j\}) + f(V \setminus \{j^*\}) - f(S) - f(V) \right\} =: g^{\text{low}}(t). \end{aligned}$$

If $\gamma < g^{\text{low}}(1)$, we obtain $\frac{d}{dt} g^{\text{low}}(t) = f(S \cup \{j\}) + f(V \setminus \{j^*\}) - f(S) - f(V) > 0$ and thus $\theta^{(2)} = \frac{\gamma - f(S)}{f(S \cup \{j\}) + f(V \setminus \{j^*\}) - f(S) - f(V)}$. Otherwise, we have $\theta^{(2)} \geq 1$.

Next, we suppose that $g^{\text{low}}(1) \leq \gamma$ and $1 \leq t$. The different components of $\mathbf{y}(t)$ are ordered as $t \geq 1 > 0 \geq -t$ and $\mathbf{y}(t)$ can be represented as

$$\mathbf{y}(t) = (t - 1) \cdot \mathbf{I}_{\{j\}} + 1 \cdot \mathbf{I}_{S \cup \{j\}} + t \cdot \mathbf{I}_{V \setminus \{j^*\}} + (-t) \cdot \mathbf{I}_V.$$

Thus, the value of $\hat{f}(\mathbf{y}(t))$ is given by

$$\begin{aligned} \hat{f}(\mathbf{y}(t)) &= (t - 1) \cdot f(\{j\}) + 1 \cdot f(S \cup \{j\}) + t \cdot f(V \setminus \{j^*\}) + (-t) \cdot f(V) \\ &= f(S \cup \{j\}) - f(\{j\}) + t \cdot \left\{ f(\{j\}) + f(V \setminus \{j^*\}) - f(V) \right\} =: g^{\text{high}}(t). \end{aligned}$$

On the assumption that $g^{\text{low}}(1) \leq \gamma$, $\theta^{(2)}$ is bounded if and only if $\frac{d}{dt} g^{\text{high}}(t) = f(\{j\}) + f(V \setminus \{j^*\}) - f(V) > 0$. As a result, we obtain

$$\theta^{(2)} = \begin{cases} \frac{\gamma - f(S)}{f(S \cup \{j\}) + f(V \setminus \{j^*\}) - f(S) - f(V)} & \text{if } \gamma < g^{\text{low}}(1), \\ \frac{\gamma - f(S \cup \{j\}) + f(\{j\})}{f(\{j\}) + f(V \setminus \{j^*\}) - f(V)} & \text{if } \gamma \geq g^{\text{low}}(1) \text{ and } \frac{d}{dt} g^{\text{high}}(t) > 0, \\ +\infty & \text{if } \gamma \geq g^{\text{low}}(1) \text{ and } \frac{d}{dt} g^{\text{high}}(t) \leq 0. \end{cases}$$

Note that $g^{\text{low}}(1) = g^{\text{high}}(1)$, $\frac{d}{dt} g^{\text{low}}(t) \leq \frac{d}{dt} g^{\text{high}}(t)$ and $\hat{f}(\mathbf{y}(t)) = \min\{g^{\text{low}}(t), g^{\text{high}}(t)\}$ for all $t \geq 0$.

Algorithm 3 Description of the algorithm by Nemhauser and Wolsey.

```

1: Let  $Q_1 = \{T_1, \dots, T_m\}$  be a set of distinct subsets of  $V$ .
2: Set  $\text{stop} \leftarrow \text{false}$  and  $i \leftarrow 1$ .
3: while  $\text{stop} = \text{false}$  do
4:   Solve the MIP problem (S1) with respect to  $Q_i$ , and let  $(\eta_i, \mathbf{I}_{S_i})$  be an optimal solution.
5:   if  $f(S_i) = \eta_i$  then
6:      $\text{stop} \leftarrow \text{true}$  ( $S_i$  is an optimal solution and  $\eta_i$  the optimal value).
7:   else
8:     Set  $Q_{i+1} \leftarrow Q_i \cup \{S_i\}$  and  $i \leftarrow i + 1$ 
9:   end if
10: end while

```

Remark: If $f(S) = \gamma$, then $\theta^{(2)}$ can be equal to 0. In such a case, we choose a small $\delta > 0$ and replace $\theta^{(2)}$ by δ so that the resulting submodularity cut H satisfies Lemma 4.

A.3 Computation of $\theta^{(3)}$

We have $\theta^{(3)} = \max\{t \geq 0 : \hat{f}(\mathbf{y}(t)) \leq \gamma\}$, where $\mathbf{y}(t) := \mathbf{I}_S - t \cdot \mathbf{e}_{j^*}$. Note that $f(S) = \hat{f}(\mathbf{y}(0)) \leq \gamma$. Consider a parameter $t \geq 0$. The different components of $\mathbf{y}(t)$ are ordered as $1 > 0 \geq -t$ and $\mathbf{y}(t)$ can be represented as

$$\mathbf{y}(t) = 1 \cdot \mathbf{I}_S + t \cdot \mathbf{I}_{V \setminus \{j^*\}} + (-t) \cdot \mathbf{I}_V.$$

Thus, the value of $\hat{f}(\mathbf{y}(t))$ is given by

$$\hat{f}(\mathbf{y}(t)) = 1 \cdot f(S) + t \cdot f(V \setminus \{j^*\}) + (-t) \cdot f(V) = f(S) + t \{f(V \setminus \{j^*\}) - f(V)\}.$$

So, $\theta^{(3)}$ is bounded if and only if $\frac{d}{dt} \hat{f}(\mathbf{y}(t)) = f(V \setminus \{i\}) - f(V) > 0$. Thus, we have

$$\theta^{(3)} = \begin{cases} \frac{\gamma - f(S)}{f(V \setminus \{j^*\}) - f(V)} & \text{if } f(V \setminus \{i\}) - f(V) > 0, \\ +\infty & \text{otherwise.} \end{cases}$$

In particular, if f is nondecreasing, it holds that $f(V \setminus \{i\}) \leq f(V)$ and thus we have $\theta^{(3)} = +\infty$.

B Outline of the algorithm by Nemhauser & Wolsey

Throughout this section, we assume that $f : 2^V \rightarrow \mathbb{R}$ is nondecreasing. Nemhauser and Wolsey [16] showed that the submodular maximization problem

$$\max_{S \subseteq V} f(S) \quad \text{s. t. } |S| \leq k \quad (1)$$

can be reformulated as

$$\begin{aligned} \max_{\eta, \mathbf{y}} \quad & \eta \\ \text{s. t.} \quad & \eta \leq f(S) + \sum_{j \in V \setminus S} \rho_j(S) y_j, \quad \forall S \in 2^V, \\ & \sum_{j \in V} y_j = k, \quad y_j \in \{0, 1\}, \quad \forall j \in V, \end{aligned} \quad (10)$$

where $\rho_j(S) := f(S \cup \{j\}) - f(S)$. Specifically, $(\eta, \mathbf{y}) = (f(S), \mathbf{I}_S)$ is an optimal solution to (10) if and only if S is an optimal solution to (1). Let us denote the optimal value of (10) by η^* . The problem (10) is a mixed integer program (MIP) with $O(2^n)$ inequalities, and it would be intractable because of the number of constraints.

We describe the algorithm of Nemhauser and Wolsey [16] for the submodular maximization problem (1). Initially, we let $Q_1 = \{T_1, \dots, T_m\}$ be a set of distinct subsets of V , and set $i \leftarrow 1$. In iteration $i \geq 1$, solve the following (relatively small) MIP

$$\begin{aligned} \max_{\eta, \mathbf{y}} \quad & \eta \\ \text{s. t.} \quad & \eta \leq f(S) + \sum_{j \in V \setminus S} \rho_j(S) y_j, \quad \forall S \in Q_i = \{T_1, \dots, T_m, S_1, \dots, S_{i-1}\}, \\ & \sum_{j \in V} y_j = k, \quad y_j \in \{0, 1\}, \quad \forall j \in V, \end{aligned} \quad (\text{S1})$$

and let $(\eta_i, \mathbf{I}_{S_i})$ be an optimal solution to (S1). Since the feasible region of (S1) is larger than or equal to that of (10), η_i is an upper bound on η^* . Thus, we have $f(S_i) \leq \eta^* \leq \eta_i$. Therefore, if $f(S_i) = \eta_i$, S_i is an optimal solution to the submodular maximization problem. If $f(S_i) < \eta_i$, set $Q_{i+1} \leftarrow Q_i \cup \{S_i\}$, $i \leftarrow i + 1$ and execute the next iteration. The description of the algorithm is given in Alg. 3. It terminates after at most $\binom{n}{k}$ iterations.

Note that $\eta_1 \geq \eta_2 \geq \dots \geq \eta^*$. Thus, Alg. 3 can also be regarded as a subroutine just for the nonincreasing upper bound η_i .
