A Derivation of the Minimax Forecaster

In this appendix, we outline how the Minimax Forecaster is derived, as well as its associated guarantees. This outline closely follows the exposition in [10, Chapter 8], to which we refer the reader for some of the technical derivations.

First, we note that the Minimax Forecaster as presented in [10] actually refers to a slightly different setup than ours, where the outcome space is $\mathcal{Y} = \{0, 1\}$ and the prediction space is $\mathcal{P} = [0, 1]$, rather than $\mathcal{Y} = \{-1, +1\}$ and $\mathcal{P} = [-1, +1]$. We will first derive the forecaster for the first setting, and then show how to convert it to the second setting.

Our goal is to find a predictor which minimizes the worst-case regret,

$$
\max_{\mathbf{y}\in\{0,1\}^T}\left(L(\mathbf{p},\mathbf{y})-\inf_{\mathbf{f}\in\mathcal{F}}L(\mathbf{f},\mathbf{y})\right)
$$

where $\mathbf{p} = (p_1, \ldots, p_T)$ is the prediction sequence.

For convenience, in the following we sometimes use the notation y^t to denote a vector in $\{0,1\}^t$. The idea of the derivation is to work backwards, starting with computing the optimal prediction at the last round T, then deriving the optimal prediction at round $T-1$ and so on. In the last round T, the first $T-1$ outcomes y^{T-1} have been revealed, and we want to find the optimal prediction p_T . Since our goal is to minimize worst-case regret with respect to the absolute loss, we just need to compute p_T which minimizes

$$
\max \Big\{ L(\mathbf{p}^{T-1}, \mathbf{y}^{T-1}) + p_T - \inf_{\mathbf{f} \in \mathcal{F}} L(\mathbf{f}, \mathbf{y}^{T-1} \mathbf{0}), \ L(\mathbf{p}^{T-1}, \mathbf{y}^{T-1}) + (1 - p_T) - \inf_{\mathbf{f} \in \mathcal{F}} L(\mathbf{f}, \mathbf{y}^{T-1} \mathbf{1}) \Big\}.
$$

In our setting, it is not hard to show that $\left|\inf_{\mathbf{f}\in\mathcal{F}} L(\mathbf{f}, \mathbf{y}^{t-1}0) - \inf_{\mathbf{f}\in\mathcal{F}} L(\mathbf{f}, \mathbf{y}^{t-1}1)\right| \leq 1$ (see [10, Lemma 8.1]). Using this, we can compute the optimal p_T to be

$$
p_T = \frac{1}{2} \Big(A_T (\mathbf{y}^{T-1} \mathbf{1}) - A_T (\mathbf{y}^{T-1} \mathbf{0}) + 1 \Big) \tag{5}
$$

where $A_T(\mathbf{y}^T) = -\inf_{\mathbf{f} \in \mathcal{F}} L(\mathbf{f}, \mathbf{y}^T)$.

Having determined p_T , we can continue to the previous prediction p_{T-1} . This is equivalent to minimizing

$$
\max \Big\{ L(\mathbf{p}^{T-2}, \mathbf{y}^{T-2}) + p_{T-1} + A_{T-1}(\mathbf{y}^{T-2} \mathbf{0}), \ L(\mathbf{p}^{T-1}, \mathbf{y}^{T-1}) + (1 - p_{T-1}) - \inf_{\mathbf{f} \in \mathcal{F}} L(\mathbf{f}, \mathbf{y}^{T-1} \mathbf{1}) \Big\}
$$

where

$$
A_{t-1}(\mathbf{y}^{t-1}) = \min_{p_t \in [0,1]} \max \left\{ p_t - \inf_{\mathbf{f} \in \mathcal{F}} L(\mathbf{f}, \mathbf{y}^{t-1} \mathbf{0}) \; , \; (1 - p_t) - \inf_{\mathbf{f} \in \mathcal{F}} L(\mathbf{f}, \mathbf{y}^{t-1} \mathbf{1}) \right\} . \tag{6}
$$

Note that by plugging in the value of p_T from Eq. (5), we also get the following equivalent formulation for $A_{T-1}(\mathbf{y}^{T-1})$:

$$
A_{T-1}(\mathbf{y}^{T-1}) = \frac{1}{2} \Big(A_T(\mathbf{y}^{T-1}0) + A_T(\mathbf{y}^{T-1}1) + 1 \Big).
$$

Again, it is possible to show that the optimal value of p_{T-1} is

$$
p_{T-1} = \frac{1}{2} \Big(A_{T-1} (\mathbf{y}^{T-2}1) - A_T (\mathbf{y}^{T-2}0) + 1 \Big).
$$

Repeating this procedure, one can show that at any round t , the minimax optimal prediction is

$$
p_t = \frac{1}{2} \left(A_t(\mathbf{y}^{t-1}1) - A_t(\mathbf{y}^{t-1}0) + 1 \right)
$$
\n(7)

where A_t is defined recursively as $A_T(\mathbf{y}^T) = -\inf_{\mathbf{f} \in \mathcal{F}} L(\mathbf{f}, \mathbf{y}^T)$ and

$$
A_{t-1}(\mathbf{y}^{t-1}) = \frac{1}{2} \Big(A_t(\mathbf{y}^{t-1}0) + A_t(\mathbf{y}^{t-1}1) + 1 \Big). \tag{8}
$$

for all t .

At first glance, computing p_t from Eq. (7) might seem tricky, since it requires computing $A_t(\mathbf{y}^t)$ whose recursive expansion in Eq. (8) involves exponentially many terms. Luckily, the recursive expansion has a simple structure, and it is not hard to show that

$$
A_t(\mathbf{y}^t) = \frac{T-t}{2} - \frac{1}{2^T} \sum_{\mathbf{y} \in \{0,1\}^T} \left(\inf_{\mathbf{f} \in \mathcal{F}} L(\mathbf{f}, \mathbf{y}^t Y^{T-t}) \right) = \frac{T-t}{2} - \mathbb{E} \Big[\inf_{\mathbf{f} \in \mathcal{F}} L(\mathbf{f}, \mathbf{y}^t Y^{T-t}) \Big] \tag{9}
$$

where Y^{T-t} is a sequence of $T-t$ i.i.d. Bernoulli random variables, which take values in {0, 1} with equal probability. Plugging this into the formula for the minimax prediction in Eq. (7) , we get that³

$$
p_t = \frac{1}{2} \left(\mathbb{E} \left[\inf_{\mathbf{f} \in \mathcal{F}} L(\mathbf{f}, \mathbf{y}^{t-1} \mathbf{0} Y^{T-t}) - \inf_{\mathbf{f} \in \mathcal{F}} L(\mathbf{f}, \mathbf{y}^{t-1} \mathbf{1} Y^{T-t}) \right] + 1 \right). \tag{10}
$$

This prediction rule constitutes the Minimax Forecaster as presented in [10].

After deriving the algorithm, we turn to analyze its regret performance. To do so, we just need to note that A_0 equals the worst-case regret —see the recursive definition at Eq. (6). Using the alternative explicit definition in Eq. (9), we get that the worst-case regret equals

$$
\frac{T}{2} - \mathbb{E}\left[\inf_{\mathbf{f}\in\mathcal{F}}\sum_{t=1}^{T}|f_t - Y_t|\right] = \mathbb{E}\left[\sup_{\mathbf{f}\in\mathcal{F}}\sum_{t=1}^{T}\left(\frac{1}{2}-|f_t - Y_t|\right)\right] = \mathbb{E}\left[\sup_{\mathbf{f}\in\mathcal{F}}\sum_{t=1}^{T}\left(f_t - \frac{1}{2}\right)\sigma_t\right]
$$

where σ_t are i.i.d. Rademacher random variables (taking values of -1 and $+1$ with equal probability). Recalling the definition of Rademacher complexity, Eq. (2), we get that the regret is bounded by the Rademacher complexity of the shifted class, which is obtained from F by taking every $f \in \mathcal{F}$ and replacing every coordinate f_t by $f_t - 1/2$.

Finally, it remains to show how to convert the forecaster and analysis above to the setting discussed in this paper, where the outcomes are in $\{-1, +1\}$ rather than $\{0, 1\}$ and the predictions are in $[-1, +1]$ rather than [0,1]. To do so, consider a learning problem in this new setting, with some class F. For any vector y, define \tilde{y} to be the shifted vector $(y + 1)/2$, where $1 = (1, ..., 1)$ is the all-ones vector. Also, define $\widetilde{\mathcal{F}}$ to be the shifted class $\widetilde{\mathcal{F}} = \{(\mathbf{f} + \mathbf{1})/2 : \mathbf{f} \in \mathcal{F}\}\.$ It is easily seen that $L(\mathbf{f}, \mathbf{y}) = 2L(\widetilde{\mathbf{f}}, \widetilde{\mathbf{y}})$ for any \mathbf{f}, \mathbf{y} . As a result, if we look at the prediction p_t given by our forecaster in Eq. (3), then $\tilde{p}_t = (p_t + 1)/2$ is the minimax optimal prediction given by Eq. (10) with respect to the class $\widetilde{\mathcal{F}}$ and the outcomes $\widetilde{\mathbf{y}}^T$. So our analysis above applies, and we get that

$$
\max_{\mathbf{y} \in \{-1, +1\}^T} \left(L(\mathbf{p}, \mathbf{y}) - \inf_{\mathbf{f} \in \mathcal{F}} L(\mathbf{f}, \mathbf{y}) \right) = \max_{\tilde{\mathbf{y}} \in [0, 1]^T} 2 \left(L(\tilde{\mathbf{p}}, \tilde{\mathbf{y}}) - \inf_{\tilde{\mathbf{f}} \in \tilde{\mathcal{F}}} L(\tilde{\mathbf{f}}, \tilde{\mathbf{y}}) \right)
$$

\n
$$
= 2 \mathbb{E} \left[\sup_{\tilde{\mathbf{f}} \in \tilde{\mathcal{F}}} \sum_{t=1}^T \left(\tilde{f}_t - \frac{1}{2} \right) \sigma_t \right]
$$

\n
$$
= \mathbb{E} \left[\sup_{\mathbf{f} \in \mathcal{F}} \sum_{t=1}^T \sigma_t f_t \right]
$$

which is exactly the Rademacher complexity of the class \mathcal{F} .

B Proof of Thm. 3

Let $Y(t)$ denote the set of Bernoulli random variables chosen at round t. Let \mathbb{E}_{z_t} denote expectation with respect to z_t , conditioned on $z_1, Y(1), \ldots, z_{t-1}, Y(t-1)$ as well as $Y(t)$. Let $\mathbb{E}_{Y(t)}$ denote the expectation with respect to the random drawing of $Y(t)$, conditioned on $z_1, Y(1), \ldots, z_{t-1}, Y(t-1)$.

We will need two simple observations. First, by convexity of the loss function, we have that for any $p_t, f_t, y_t, \ell(p_t, y_t) - \ell(f_t, y_t) \leq (p_t - f_t) \partial_{p_t} \ell(p_t, y_t)$. Second, by definition of r_t and

³This fact appears in an implicit form in $[9]$ —see also [10, Exercise 8.4].

 z_t , we have that for any fixed p_t , f_t ,

$$
\frac{1}{\rho b}(p_t - f_t)\partial_{p_t}\ell(p_t, y_t) = \frac{1}{b}(p_t - f_t)(1 - 2r_t)
$$
\n
$$
= \frac{1}{b}r_t(f_t - p_t) + \frac{1}{b}(1 - r_t)(p_t - f_t)
$$
\n
$$
= r_t(\tilde{f}_t - \tilde{p}_t) + (1 - r_t)(\tilde{p}_t - \tilde{f}_t)
$$
\n
$$
= r_t((1 - \tilde{p}_t) - (1 - \tilde{f}_t)) + (1 - r_t)((\tilde{p}_t + 1) - (\tilde{f}_t + 1))
$$
\n
$$
= \mathbb{E}_{z_t} [|\tilde{p}_t - z_t| - |\tilde{f}_t - z_t|].
$$

The last transition uses the fact that $\widetilde{p}_t, \widetilde{f}_t \in [-1, +1]$. By these two observations, we have

$$
\sum_{t=1}^{T} \ell(p_t, y_t) - L(\mathbf{f}, \mathbf{y}) \le \sum_{t=1}^{T} (p_t - f_t) \, \partial_{p_t} \ell(p_t, y_t) = \rho \, b \, \sum_{t=1}^{T} \mathbb{E}_{z_t} \left[|\widetilde{p}_t - z_t| - \left| \widetilde{f}_t - z_t \right| \right] \quad (11)
$$

Now, note that $|\widetilde{p}_t - z_t| - |\widetilde{f}_t - z_t| - \mathbb{E}_{z_t} [|\widetilde{p}_t - z_t| - |\widetilde{f}_t - z_t|]$ for $t = 1, ..., T$ is a martingale difference sequence for any values of $z \propto V(1) - \widetilde{V}(t-1) V(t)$ (which fixes \widetilde{z}), the difference sequence: for any values of $z_1, Y(1), \ldots, z_{t-1}, Y(t-1), Y(t)$ (which fixes \tilde{p}_t), the conditional expectation of this expression over z_t is zero. Using Azuma's inequality we can conditional expectation of this expression over z_t is zero. Using Azuma's inequality, we can upper bound Eq. (11) with probability at least $1 - \delta/2$ by

$$
\rho b \sum_{t=1}^{T} \left(|\widetilde{p}_t - z_t| - |\widetilde{f}_t - z_t| \right) + \rho b \sqrt{8T \ln(2/\delta)}.
$$
\n(12)

.

The next step is to relate Eq. (12) to $\rho b \sum_{t=1}^T (|\mathbb{E}_{Y(t)}[\tilde{p}_t] - z_t| - |\tilde{f}_t - z_t|)$. It might be terming to appeal to Azuma's inequality again. Unfortunately there is no martingale tempting to appeal to Azuma's inequality again. Unfortunately, there is no martingale difference sequence here, since z_t is itself a random variable whose distribution is influenced by $Y(t)$. Thus, we need to turn to coarser methods. Eq. (12) can be upper bounded by

$$
\rho b \sum_{t=1}^{T} \left(\left| \mathbb{E}_{Y(t)}[\widetilde{p}_t] - z_t \right| - \left| \widetilde{f}_t - z_t \right| \right) + \rho b \sum_{t=1}^{T} \left| \widetilde{p}_t - \mathbb{E}_{Y(t)}[\widetilde{p}_t] \right| + \rho b \sqrt{8T \ln(2/\delta)}. \tag{13}
$$

Recall that \widetilde{p}_t is an average over ηT i.i.d. random variables, with expectation $\mathbb{E}_{Y(t)}[\widetilde{p}_t]$.
By Hoeffding's inequality, this implies that for any $t-1$, T with probability at least By Hoeffding's inequality, this implies that for any $t = 1, \ldots, T$, with probability at least $1 - \delta/2T$ over the choice of $Y(t)$, $|\widetilde{p}_t - \mathbb{E}_{Y(t)}[\widetilde{p}_t]| \leq \sqrt{2\ln(2T/\delta)/(\eta T)}$. By a union bound, it follows that with probability at least $1 - \delta/2$ over the choice of $Y(1), \ldots, Y(T)$,

$$
\sum_{t=1}^{T} |\widetilde{p}_t - \mathbb{E}_{Y(t)}[\widetilde{p}_t]| \le \sqrt{\frac{2T\ln(2T/\delta)}{\eta}}
$$

Combining this with Eq. (13), we get that with probability at least $1 - \delta$,

$$
\rho b \sum_{t=1}^{T} \left(\left| \mathbb{E}_{Y(t)}[\widetilde{p}_t] - z_t \right| - \left| \widetilde{f}_t - z_t \right| \right) + \rho b \sqrt{\frac{2T \ln(2T/\delta)}{\eta}} + \rho b \sqrt{8T \ln(2/\delta)} \ . \tag{14}
$$

Finally, by definition of $\tilde{p}_t = p_t/b$, we have

$$
\mathbb{E}_{Y(t)}[\widetilde{p}_t] = \mathbb{E}_{Y(t)}\left[\inf_{\mathbf{f}\in\mathcal{F}} L\left(\widetilde{\mathbf{f}}, z_1 \ldots z_{t-1} \left(-1\right) Y_{t+1} \ldots Y_T\right) - \inf_{\mathbf{f}\in\mathcal{F}} L\left(\widetilde{\mathbf{f}}, z_1 \ldots z_{t-1} \mathbf{1} Y_{t+1} \ldots Y_T\right)\right].
$$

This is exactly the Minimax Forecaster's prediction at round t , with respect to the sequence of outcomes $z_1, \ldots, z_{t-1} \in \{-1, +1\}$, and the class $\tilde{\mathcal{F}} := \{\tilde{\mathbf{f}} : \mathbf{f} \in \mathcal{F}\} \subseteq [-1, 1]^T$. Therefore, using Thm. 1, we can upper bound Eq. (14) by

$$
\rho b \mathcal{R}_T(\widetilde{\mathcal{F}}) + \rho b \sqrt{\frac{2T \ln(2T/\delta)}{\eta}} + \rho b \sqrt{8T \ln(2/\delta)}.
$$

By definition of $\widetilde{\mathcal{F}}$ and Rademacher complexity, it is straightforward to verify that $\mathcal{R}_T(\widetilde{\mathcal{F}})$ = $\frac{1}{b}R_T(\mathcal{F})$. Using that to rewrite the bound, and slightly simplifying for readability, the result stated in the theorem follows.

C Proof of Lemma 1

The proof assumes that the infimum and supremum of certain functions over \mathcal{Y}, \mathcal{F} are attainable. If not, the proof can be easily adapted by finding attainable values which are ϵ -close to the infimum or supremum, and then taking $\epsilon \to 0$.

For the purpose of contradiction, suppose there exists a strategy for the adversary and a round $r \leq T$ such that at the end of round r, the forecaster suffers a regret $G' > G$ with probability larger than δ . Consider the following modified strategy for the adversary: the adversary plays according to the aforementioned strategy until round r . It then computes

$$
f^* = \underset{f \in \mathcal{F}}{\operatorname{argmin}} \sum_{t=1}^r \ell(f_t, y_t) .
$$

At all subsequent rounds $t = r + 1, r + 2, ..., T$, the adversary chooses

$$
y_t^* = \underset{y \in \mathcal{Y}}{\operatorname{argmax}} \inf_{p \in \mathcal{P}} (\ell(p, y) - \ell(f_t^*, y)).
$$

By the assumption on the loss function,

$$
\ell(p_t, y_t^*) - \ell(f_t^*, y_t^*) \ge \inf_{p \in \mathcal{P}} (\ell(p, y_t^*) - \ell(f_t^*, y_t^*)) = \sup_{y \in \mathcal{Y}} \inf_{p \in \mathcal{P}} (\ell(p, y) - \ell(f_t^*, y)) \ge 0.
$$

Thus, the regret over all T rounds, with respect to f^* , is

$$
\sum_{t=1}^r \left(\ell(p_t, y_t) - \ell(f_t^*, y_t)\right) + \sum_{t=r+1}^T \left(\ell(p_t, y_t^*) - \ell(f_t^*, y_t^*)\right) \ge \sum_{t=1}^r \ell(p_t, y_t) - \inf_{f \in \mathcal{F}} \sum_{t=1}^r \ell(f_t, y_t) + 0
$$

which is at least G' with probability larger than δ . On the other hand, we know that the learner's regret is at most most G with probability at least $1 - \delta$. Thus we have a contradiction and the proof is concluded.
