#### Abstract

This paper contains proof details omitted from the main paper as well as a more detailed discussion of the ambiguity of STD $_{\text {min }}$-teaching.

## A Proof of Theorem 9

Theorem 9 Let $T^{n}$ be an antichain teacher for $\mathcal{P}_{n}$ and suppose $\operatorname{ord}\left(T^{n}\right) \leq \operatorname{ord}(T)$ for all antichain teachers $T$ for $\mathcal{P}_{n}$. Then, for all but finitely many $n$, we have $0.22 \cdot n<\operatorname{ord}\left(T^{n}\right)<0.23 \cdot n$.

To establish this result, we first introduce some notation and some background on bipartite matching.
Definition 21 Let $\mathcal{C}$ be any concept class. The antichain number of $\mathcal{C}$, denoted by $\operatorname{ACN}(\mathcal{C})$, is the smallest possible order of a teacher for $\mathcal{C}$ with the antichain property.

Theorem 9 can then be restated as follows:

$$
\text { For all but finitely many } n \text {, we have } 0.22 \cdot n<\operatorname{ACN}\left(\mathcal{P}_{n}\right)<0.23 \cdot n \text {. }
$$

It is well known that a bipartite graph all of whose vertices have the same degree contains a perfect matching. The simple proof is based on a double counting argument. The same kind of argument can be used to show the following (most likely also well known) result:

Lemma 22 Let $G=\left(V_{1}, V_{2}, E\right)$ be a bipartite graph with vertex sets $V_{1}$ and $V_{2}$. Suppose that every vertex in $V_{1}$ has degree $d_{1}$ while every vertex in $V_{2}$ has degree $d_{2} \leq d_{1}$. Then $G$ contains a matching of size $\left|V_{1}\right|$.

Proof. For $U \subseteq V_{1}, \Gamma(U)$ denotes the neighborhood of $U$, i.e., $\Gamma(U)=\left\{v \in V_{1} \mid v\right.$ is adjacent to some vertex in $U\}$. It suffices to show that Hall's condition,

$$
\forall U \subseteq V_{1}:|\Gamma(U)| \geq|U|
$$

is satisfied. Fix a set $U \subseteq V_{1}$. The number of edges having one endpoint in $U$ equals $d_{1} \cdot|U|$. The number of edges having one endpoint in $\Gamma(U)$ is at most $d_{2} \cdot|\Gamma(U)|$. An edge with an endpoint in $U$ must have its other endpoint in $\Gamma(U)$. Hence $d_{1} \cdot|U| \leq d_{2} \cdot|\Gamma(U)|$. Since $d_{2} \leq d_{1}$, we may conclude that $|U| \leq|\Gamma(U)|$.

Corollary 23 Let $d, n$ be integers such that $1 \leq d \leq(n+1) / 2$. Let $X$ be a set of size $n$. Let $G=\left(V_{1}, V_{2}, E\right)$ be the bipartite graph such that

- $V_{1}\left(\right.$ resp. $\left.V_{2}\right)$ consists of all subsets of $X$ with $d-1$ (resp. d) elements,
- a set $U \in V_{1}$ is adjacent to a set $U^{\prime} \in V_{2}$ iff $U \subseteq U^{\prime}$.

Then $G$ contains a a matching of size $\left|V_{1}\right|$.
Proof. Each vertex in $V_{1}$ has degree $n-d+1$ whereas each vertex in $V_{2}$ has degree $d$. Since $d \leq(n+1) / 2$, by assumption, it follows that $d \leq n-d+1$. Now apply Lemma 22 .

Let $X$ be a set of size $n$. A sample set over $X$ is said to be conflict-free if it does not contain both $(x, 0)$ and $(x, 1)$ for some $x \in X$. Let $\mathcal{F}_{\leq d, n}$ be the family of all conflict-free sample sets over $X$ with $d$ or fewer elements. The conflict-free sample sets with exactly $d$ elements form an antichain denoted by $\mathcal{F}_{=d, n}$ in the sequel - in $\mathcal{F}_{\leq d}$. Obviously
$\mathcal{F}_{=d, n}=\left\{\left(x_{1}, b_{1}\right), \ldots,\left(x_{d}, b_{d}\right): x_{1}, \ldots, x_{d}\right.$ are $d$ distinct elements of $X$ and $\left.b_{1}, \ldots, b_{d} \in\{0,1\}\right\}$
and therefore the antichain $\mathcal{F}_{=d, n}$ is of size $\binom{n}{d} \cdot 2^{d}$.
The following result is a relative of Sperner's Theorem:
Lemma $24 \mathcal{F}_{=d, n}$ is a maximum antichain in $\mathcal{F}_{\leq d, n}$.
Proof. An antichain $\mathcal{A}^{\prime}$ with conflict-free sets $A_{1}^{\prime}, \ldots, A_{s^{\prime}}^{\prime}$ (without repetition) is called an extension of another antichain $\mathcal{A}$ with conflict-free sets $A_{1}, \ldots, A_{s}$ (again without repetition) if $s^{\prime}=s$ and $A_{i} \subseteq A_{i}^{\prime}$ for $i=1, \ldots, s$ (after renumbering the sets in $\mathcal{A}^{\prime}$ if necessary). We show, by induction on $d$, that every antichain $\mathcal{A}$ with sets taken from $\mathcal{F}_{\leq d, n}$ has an extension $\mathcal{A}^{\prime}$ with sets taken from $\mathcal{F}_{=d, n}$. For $d=1$, this is obviously true. Let $d \geq 2$ and assume inductively that it holds for $d-1$. Fix an antichain $\mathcal{A}$ with sets taken from $\mathcal{F}_{<d}, n$. Let $\mathcal{A}_{1}$ be the antichain consisting of the sets of size at most $d-1$ in $\mathcal{A}$ and let $\mathcal{A}_{2}=\mathcal{A} \backslash \overline{\mathcal{A}^{\prime}}$. By our inductive assumption, there is an extension $\mathcal{A}_{1}^{\prime}$ of $\mathcal{A}_{1}$ whose sets are taken from $\mathcal{F}_{\leq d-1, n}$. The inductive proof can now be accomplished by proving the following assertions:

Claim 1: $\mathcal{A}_{1}^{\prime} \cup \mathcal{A}_{2}$ is an antichain in $\mathcal{F}_{\leq d, n}$ whose sets are of size $d-1$ or $d$.
Claim 2: Any antichain $\mathcal{B}$ with sets of size $d-1$ or $d$ has an extension $\mathcal{B}^{\prime}$ with sets taken from $\mathcal{F}_{\leq d, n}$.

Claim 1 becomes obvious from the following observations:

- No set in $\mathcal{A}_{2}$ (with $d$ elements) can be a subset of some set in $\mathcal{A}_{1}^{\prime}$ (with $d-1$ elements).
- Since no set in $\mathcal{A}_{1}$ is a subset of some set in $\mathcal{A}_{2}$ (by the antichain property of $\mathcal{A}$ ), no set in the extension $\mathcal{A}_{1}^{\prime}$ is a subset of some set in $\mathcal{A}_{2}$.

As for proving Claim 2, fix some antichain $\mathcal{B}$. Let $\mathcal{B}=\mathcal{B}_{1} \cup \mathcal{B}_{2}$ be the decomposition of $\mathcal{B}$ into sets of size $d-1$ and sets of size $d$, respectively. A set of $\mathcal{B}_{1}$ is of the form $B=\left\{\left(x_{1}, b_{1}\right), \ldots,\left(x_{d-1}, b_{d-1}\right)\right\}$. Let $M$ be the matching of size $\left|V_{1}\right|$, whose existence is guaranteed by Corollary 23 . Pick $x_{d}$ such that $\left\{x_{1}, \ldots, x_{d-1}, x_{d}\right\}$ is the $M$-partner of $\left\{x_{1}, \ldots, x_{d-1}\right\}$. Then the set

$$
B^{\prime}=\left\{\left(x_{1}, b_{1}\right), \ldots,\left(x_{d-1}, b_{d-1}\right),\left(x_{d}, 0\right)\right\}
$$

is called the $M$-partner of $B$. Note here that different sets from $\mathcal{B}_{1}$ have different $M$-partners. Let $\mathcal{B}_{1}^{\prime}$ be the antichain obtained from $\mathcal{B}_{1}$ by replacing each set $B$ in $\mathcal{B}_{1}$ by its $M$-partner and let $\mathcal{B}^{\prime}=\mathcal{B}_{1}^{\prime} \cup \mathcal{B}_{2}$. By construction, all sets in $\mathcal{B}^{\prime}$ are of size $d$. In order to show that $\mathcal{B}^{\prime}$ is an antichain that extends $\mathcal{B}$, it suffices to show that no $M$-partner of a set $B \in \mathcal{B}_{1}$ can be equal to one of the sets in $\mathcal{B}_{2}$. But this is obvious because $B$ is a subset of its $M$-partner, but not a subset of any set in $\mathcal{B}_{2}$ (by the antichain property of $\mathcal{B}$ ). Claim 2 follows from this discussion, which also completes the proof of the lemma.

Corollary 25 Let $d_{0}=d_{0}(n)$ be the smallest $d$ such that $2^{d} \cdot\binom{n}{d} \geq 2^{n}$. Let $G=\left(V_{1}, V_{2}, E\right)$ be the bipartite graph given by (i) $V_{1}=\mathcal{F}_{=n, n}$ and $V_{2}=\mathcal{F}_{=d_{0}, n}$, and (ii) a set $U^{\prime} \in V_{1}$ is adjacent to a set $U \in V_{2}$ iff $U \subseteq U^{\prime}$. Then $G$ contains a matching of size $\left|V_{1}\right|$.

Proof. Each vertex in $V_{1}$ has degree $\binom{n}{d_{0}}$ whereas each vertex in $V_{2}$ has degree $2^{n-d_{0}}$. The definition of $d_{0}$ implies that $2^{n-d_{0}} \leq\binom{ n}{d_{0}}$. Now apply Lemma 22 .

Note that $\operatorname{ACN}(\mathcal{C})$ is upper-bounded by the smallest number $d$ such that the following graph $G=$ $\left(V_{1}, V_{2}, E\right)$ contains a matching $M$ that matches every vertex in $V_{1}$ : (i) $V_{1}=\mathcal{C}$ and $V_{2}=\mathcal{F}=d, n$, (ii) a concept $C \in \mathcal{C}$ is adjacent to a sample $S \in \mathcal{F}_{=d, n}$ iff it is consistent with $S$.

We now obtain a non-trivial reformulation of ACN:
Theorem 26 Let $|X|=n$ and let $d_{0}=d_{0}(n)$ be the smallest $d$ such that $2^{d} \cdot\binom{n}{d} \geq 2^{n}$. Then $\operatorname{ACN}\left(\mathcal{P}_{n}\right)=d_{0}(n)$.

Proof. Note that $\mathcal{P}_{n}$ can be identified with $\mathcal{F}_{=n, n}$ : each map $C: X \rightarrow\{0,1\}$ is identified with the full sample $\{(x, C(x)) \mid x \in X\}$. An application of Corollary 25 yields $\operatorname{ACN}\left(\mathcal{P}_{n}\right) \leq d_{0}(n)$.
Set $d=\operatorname{ACN}\left(\mathcal{P}_{n}\right)$. Then the maximum antichain in $\mathcal{F}_{\leq d, n}$ is of size at least $\left|\mathcal{P}_{n}\right|=2^{n}$. Using Lemma 24 and the fact that $\left|\mathcal{F}_{=d, n}\right|=\binom{n}{d} \cdot 2^{d}$, this translates into $2^{d} \cdot\binom{n}{d} \geq 2^{n}$. The definition of $d_{0}(n)$ now implies that $d \geq d_{0}(n)$.
We now show that $d_{0}(n)$ is a function linear in $n$.
Lemma 27 Let $d_{0}=d_{0}(n)$ be the smallest $d$ such that $2^{d} \cdot\binom{n}{d} \geq 2^{n}$. Then $0.22 \cdot n<d_{0}(n)<0.23 \cdot n$ for all but finitely many $n$.

Proof. For $d=n / 2$, we have $\binom{n}{n / 2} \asymp \sqrt{\frac{2}{\pi n}} 2^{n}$, which is asymptotically larger than $2^{n / 2}$. We may therefore assume that $d \leq n / 2$. For such $d$, the term $\binom{n}{d}$ decreases when $d$ decreases, while $2^{n-d}$ increases. Hence it suffices to show that $2^{d} \cdot\binom{n}{d} \geq 2^{n}$ is fulfilled for large enough $n$ when $d=0.23 \cdot n$, while it is not fulfilled for large enough $n$ when $d=0.22 \cdot n$.
To this end, let $d=p n$ with $0<p \leq 1 / 2$, and rewrite $2^{d} \cdot\binom{n}{d} \geq 2^{n}$ as

$$
\frac{1}{n} \log \binom{n}{p n} \geq 1-p
$$

It is well known that the left-hand side converges to $H(p)$, where $H(\cdot)$ denotes the binary entropy. The lemma now follows from $H(0.22)<0.78=1-0.22$ and $H(0.23)>0.77=1-0.23$.

This allows us to conclude that, asymptotically, the value of $\operatorname{ACN}\left(\mathcal{P}_{n}\right)$ lies between $0.22 \cdot n$ and $0.23 \cdot n$, as claimed by Theorem 9 .

## B Other Proof Details for Section 3

Proposition 8 Let $\mathcal{C}$ be any concept class, $Z \in\{\mathrm{RTD}, \mathrm{NCTD}\}$, and $T$ any $Z$-teacher for $\mathcal{C}$. Then there is a $Z$-teacher $T^{\prime}$ for $\mathcal{C}$ with $\operatorname{ord}\left(T^{\prime}\right)=\operatorname{ord}(T)$ such that $T^{\prime}$ has the antichain property.
Proof. First, let $T$ be any NCTD-teacher for $\mathcal{C}$. For $C \in \mathcal{C}$, obtain $T^{\prime}(C)$ from $T(C)$ as follows. If each sample set in $T(C)$ has size ord $(T)$, then $T^{\prime}(C)=T(C)$. Otherwise, $T^{\prime}(C)$ results from $T(C)$ by adding examples that are consistent with $C$ to every sample set $T_{C} \in T(C)$, until the size of $T_{C}$ equals ord $(T)$. Then $T^{\prime}$ inherits the non-clashing property on $\mathcal{C}$ from $T$. Clearly, a non-clashing teacher mapping that produces only sample sets of a constant size must also fulfill the antichain property. So $T^{\prime}$ is an NCTD-teacher for $\mathcal{C}$ with the antichain property, and $\operatorname{ord}\left(T^{\prime}\right)=\operatorname{ord}(T)$.
Second, suppose $T$ is an RTD-teacher. The construction of $T^{\prime}$ is identical to that in the first case. It remains to verify that the resulting antichain teacher $T^{\prime}$ with $\operatorname{ord}\left(T^{\prime}\right)=\operatorname{ord}(T)$ is also an RTDteacher for $\mathcal{C}$. Using the notation from Definition 2, we know that, for $C \in \mathcal{C}_{i}^{\text {min }}$, the set $T(C)$ is a teaching set for $C$ wrt $\mathcal{C}_{i}$. Since adding examples (consistently with $C$ ) to $T(C)$ does not change this fact, we obtain that, for $C \in \mathcal{C}_{i}^{\text {min }}$, the set $T^{\prime}(C)$ is a teaching set for $C$ wrt $\mathcal{C}_{i}$. Hence $T^{\prime}$ is an RTD-teacher for $\mathcal{C}$.

Proposition 11 STD is not domain-monotonic. In particular, for every $n>3$, there is a concept class $\mathcal{C}$ over a domain $X=X^{\prime} \cup X^{\prime \prime}$ such that $\operatorname{STD}(\mathcal{C})=n-1$, while $\operatorname{STD}\left(\mathcal{C} \downarrow_{X^{\prime}}\right)=2$.
Proof. Let $n>3$, and let $X^{\prime}=\left\{x_{1}^{\prime}, \ldots, x_{n}^{\prime}\right\}$ and $X^{\prime \prime}=\left\{x_{1}^{\prime \prime}, \ldots, x_{n}^{\prime \prime}\right\}$. For every $J \subseteq[n]$ of size 1 or 2 , let $C_{J}$ be the concept that assigns label 1 (resp. label 0 ) to $x_{j}^{\prime}$ and $x_{j}^{\prime \prime}$ if $j \in J$ (resp. if $j \notin J$ ). Let $C_{\emptyset}$ be the concept that assigns label 0 to $x_{1}^{\prime}, \ldots, x_{n}^{\prime}$ and label 1 to $x_{1}^{\prime \prime}, \ldots, x_{n}^{\prime \prime}$. Consider now the
following concept class $\mathcal{C}$ over the domain $X=X^{\prime} \cup X^{\prime \prime}: \mathcal{C}=\left\{C_{J}|J \subseteq[n], 0 \leq|J| \leq 2\}\right.$. See Table 3 for an illustration of the case $n=5$.

Note that $\mathcal{C} \downarrow_{X^{\prime}}$ is the class of all subsets of $X$ whose size is at most 2 . It is well known [Zilles et al. 2011] that $\operatorname{STD}\left(\mathcal{C} \downarrow_{X^{\prime}}\right)=2$.
It remains to prove that $\operatorname{STD}(\mathcal{C})=n-1$. To this end, we first determine the minimum teaching sets for every concept in $\mathcal{C}$ :
(i) The minimum teaching sets for $C_{\emptyset}$ are the sets of the form $\left\{\left(x_{j}^{\prime}, 0\right),\left(x_{j}^{\prime \prime}, 1\right)\right\}$ for $j=1, \ldots, n$.
(ii) For $1 \leq i<j \leq n$, the minimum teaching sets for $C_{\{i, j\}}$ are the sets of the form $\left\{\left(u_{i}, 1\right),\left(u_{j}, 1\right)\right\}$ where $u_{i} \in\left\{x_{i}^{\prime}, x_{i}^{\prime \prime}\right\}, u_{j} \in\left\{x_{j}^{\prime}, x_{j}^{\prime \prime}\right\}$ and $\left\{u_{i}, u_{j}\right\} \cap\left\{x_{i}^{\prime}, x_{j}^{\prime}\right\} \neq \emptyset$.
(iii) For $1 \leq i \leq n$, the minimum teaching sets for $C_{\{i\}}$ are the sets of the form $\left\{\left(u_{j}, 0\right) \mid j \in\right.$ $[n] \backslash\{i\}\}$ where $u_{j} \in\left\{x_{j}^{\prime}, x_{j}^{\prime \prime}\right\}$ and, for at least one index $j^{\prime} \in[n] \backslash\{i\}$, we have $u_{j^{\prime}}=x_{j^{\prime}}^{\prime \prime}$.
For each $C \in \mathcal{C}$, let $\operatorname{TS}(C)$ be the collection of minimum teaching sets for $C$. The largest of these minimum teaching sets, namely the ones for concepts of the form $C_{\{i\}}$, are of size $n-1$. Hence $\mathrm{TD}(\mathcal{C})=n-1$. Next, we will verify the following property for every concept $C \in \mathcal{C}$ :
${ }^{(*)}$ If $S$ is a minimum teaching set for $C$ wrt $\mathcal{C}$, then every proper subset of $S$ is contained in a minimum teaching set for some concept $C^{\prime}$ wrt $\mathcal{C}$, where $C^{\prime} \in \mathcal{C}$, $C^{\prime} \neq C$.
(i) Consider an index $j \in[n]$ and a teaching set $\left\{\left(x_{j}^{\prime}, 0\right),\left(x_{j}^{\prime \prime}, 1\right)\right\} \in \operatorname{TS}\left(C_{\emptyset}\right)$. Removing $\left(x_{j}^{\prime}, 0\right)$ from this set yields a subset of one of the teaching sets for $C_{J} \neq C_{\emptyset}$ whenever $j \in J$ and $|J|=2$. A similar reasoning applies when removing $\left(x_{j}^{\prime \prime}, 1\right)$ instead of $\left(x_{j}^{\prime}, 0\right)$.
(ii) Consider indices $i \neq j \in[n]$ and a teaching set $\left\{\left(u_{i}, 1\right),\left(u_{j}, 1\right)\right\} \in \operatorname{TS}\left(C_{\{i, j\}}\right)$. Removing one example, say $\left(u_{i}, 1\right)$, from this set yields a subset of one of the teaching sets for $C_{J} \neq C_{\{i, j\}}$ whenever $j \in J, i \notin J$ and $|J|=2$.
(iii) Consider an index $i \in[n]$ and a teaching set $\left\{\left(u_{j}, 0\right) \mid j \in[n] \backslash\{i\}\right\} \in \operatorname{TS}\left(C_{\{i\}}\right)$. Removing $\left(u_{j_{0}}, 0\right)$ from this set yields a subset of one of the teaching sets for $C_{\left\{j_{0}\right\}}$.
This establishes Property $\left({ }^{*}\right)$, which immediately implies $\operatorname{STD}(\mathcal{C})=\operatorname{TD}(\mathcal{C})=n-1$.

Table 3: The concept class $\mathcal{C}$ from the proof of Proposition 11 for $n=5$. The entries in bold indicate one (arbitrarily chosen) minimum teaching set for each concept.

## C Proof Details for Section 4

Observation 1 Every subset teaching sequence of order d can be transformed into a normalized sequence $\left(T_{k}\right)_{k \in \mathbb{N}}$ of the same order, where a normalized subset teaching sequence has the property that, for every $k$ and every $C \in \mathcal{C}$, we have (i) $T_{k+1}$ differs from $T_{k}$ on exactly one concept, (ii) $\left|T_{k+1}(C)\right| \in\left\{\left|T_{k}(C)\right|-1,\left|T_{k}(C)\right|\right\}$, (iii) $\left|T_{k}(C)\right| \geq d$, which implies that $\left|T_{k^{*}}(C)\right|=d$.

Proof. Properties (i) and (ii) are easy to achieve by breaking a step from $T_{k}$ to $T_{k+1}$ into several smaller intermediate steps. Assume that (ii) holds. Then property (iii) can be achieved by omitting all steps that make $\left|T_{k}(C)\right|$ smaller than $d$. It is easy to see that the resulting sequence is again an admissible subset teaching sequence.

Proposition $13 \mathrm{STD}_{\min }(\mathcal{C}) \leq \operatorname{STD}(\mathcal{C})$, and for all $n \in \mathbb{N}$ there is some succinct $\mathcal{C}_{n}$ such that $\operatorname{STD}_{\text {min }}\left(\mathcal{C}_{n}\right)=2$ and $\operatorname{STD}(\mathcal{C})=n$.
Proof. To see that $\mathrm{STD}_{\text {min }}$ is bounded from above by STD, let $k^{*}$ be as defined in Definition 4. For each $k \leq k^{*}$, let $T_{k}(C)$ be any one set in $\operatorname{STS}^{k}(C)$ such that $T_{k^{*}}(C) \subseteq T_{k^{*}-1}(C) \subseteq \ldots \subseteq T_{1}(C)$. Such sets $T_{k}(C)$ exist by the definition of STD. Finally, set $T_{0}(C)=\{(x, C(x)) \mid x \in X\}$. Then $\mathcal{T}=\left(T_{k}\right)_{k \in \mathbb{N}}$ is a subset teaching sequence of order $\operatorname{STD}(\mathcal{C})$ for $\mathcal{C}$. So, $\operatorname{STD}_{\min }(\mathcal{C}) \leq \operatorname{STD}(\mathcal{C})$.
An example of a succinct concept class $\mathcal{C}_{n}$ as claimed is the class over a domain of size $n+1$, consisting of all concepts of size either 1 or 2 . It was shown by Zilles et al. [2011], that $\operatorname{STD}(\mathcal{C})=n$. By contrast, one can easily obtain $\mathrm{STD}_{\min }\left(\mathcal{C}_{n}\right)=2$, as illustrated in Table 4 . for any concept $C$ of size 2 , the set $T_{1}(C)$ contains only the two positively labeled instances for $C$, while $T_{1}(C)=T_{0}(C)=\{(x, C(x)) \mid x \in X\}$ if $C$ is a singleton. In the next iteration, set $T_{2}\left(\left\{x_{n}\right\}\right)=\left\{\left(x_{n}, 1\right),\left(x_{1}, 0\right)\right\}$ and $T_{2}\left(\left\{x_{i}\right\}\right)=\left\{\left(x_{i}, 1\right),\left(x_{i+1}, 0\right)\right\}$ for each singleton concept $\left\{x_{i}\right\}$ with $i \neq n$. Clearly, for all $i, T_{2}\left(\left\{x_{i}\right\}\right) \subseteq T_{1}\left(\left\{x_{i}\right\}\right)$ and $T_{2}\left(\left\{x_{i}\right\}\right) \nsubseteq T_{1}(C)$ for any $C \neq\left\{x_{i}\right\}$. Thus, we obtain a subset teaching sequence of order 2 for $\mathcal{C}$, i.e., $\operatorname{STD}_{\min }(\mathcal{C})=2$.

Table 4: The concept class $\mathcal{C}_{n}$ [Zilles et al., 2011], from the proof of Proposition 13 for the case $n=4$. The final subset teaching sets (corresponding to $T_{2}$ ) that witness $\operatorname{STD}_{\min }\left(\mathcal{C}_{n}\right)=2$ are highlighted in blue. The rightmost column shows the mapping $T_{1}$; the subsets marked in blue are not contained in any other set in that column, hence they can be used by the teacher $T_{2}$ in the next iteration. When calculating STD instead of $\mathrm{STD}_{\min }$, the teacher $T_{1}$ assigns every singleton its unique minimum teaching set, which is a set of four negative examples. These sets cannot be reduced in subsequent iterations, since their proper subsets occur in minimum teaching sets for other concepts; hence $\operatorname{STD}\left(\mathcal{C}_{4}\right)=4$.

Proposition $15 \mathrm{STD}_{\min }$ is class-monotonic, domain-monotonic, and satisfies the antichain property.
Proof. Class-monotonicity is obvious: If $\mathcal{C}, \mathcal{C}^{\prime}$ are concept classes over a fixed domain $X, \mathcal{C} \subseteq \mathcal{C}^{\prime}$, and $\mathcal{T}^{\prime}=\left(T_{k}^{\prime}\right)_{k \in \mathbb{N}}$ is a subset teaching sequence for $\mathcal{C}^{\prime}$ of order $\mathrm{STD}_{\min }\left(\mathcal{C}^{\prime}\right)$, then define $T_{k}$ to be the restriction of $T_{k}^{\prime}$ to $\mathcal{C}$. Clearly, $\mathcal{T}=\left(T_{k}\right)_{k \in \mathbb{N}}$ is a subset teaching sequence for $\mathcal{C}$ of order at most $\operatorname{STD}_{\text {min }}\left(\mathcal{C}^{\prime}\right)$. Hence $\operatorname{STD}_{\text {min }}(\mathcal{C}) \leq \operatorname{STD}_{\text {min }}\left(\mathcal{C}^{\prime}\right)$.

To establish domain-monotonicity, let $\mathcal{C}$ be any concept class over a domain $X$, and let $X^{\prime} \subseteq X$ preserve $\mathcal{C}$. Then any subset teaching sequence $\mathcal{T}^{\prime}$ for $\mathcal{C} \downarrow_{X^{\prime}}$ can be turned into a subset teaching sequence $\mathcal{T}$ for $\mathcal{C}$, by setting $T_{0}(C)=\{(x, C(x)) \mid x \in X\}$ and $T_{k}(C)=T_{k}^{\prime}(C)$ for all $C \in \mathcal{C}$ and all $k \geq 1$. Note that $\operatorname{ord}_{\mathcal{C}}(\mathcal{T})=\operatorname{ord}_{\mathcal{C}_{X^{\prime}}}\left(\mathcal{T}^{\prime}\right)$. Therefore $\mathrm{STD}_{\min }\left(\mathcal{C} \downarrow_{X^{\prime}}\right) \geq \operatorname{STD}_{\text {min }}(\mathcal{C})$.

By the definition of subset teaching sequence, it is obvious that $S T D_{\min }$ satisfies the antichain property.

## D Proof Details for Section 5

Proposition 16 For every $n \in \mathbb{N}$ there is (i) a concept class $\mathcal{C}$ with $\operatorname{STD}(\mathcal{C})=\operatorname{STD}_{\min }(\mathcal{C})=1$ and $\operatorname{NCTD}(\mathcal{C})=n$; (ii) a concept class $\mathcal{C}$ with $\operatorname{STD}(\mathcal{C})=\operatorname{STD}_{\min }(\mathcal{C})=n$ and $\operatorname{NCTD}(\mathcal{C})=\frac{n}{2}$.
Proof. (i) Consider the class $\mathcal{C}_{u}^{\text {pair }}$, as defined by Zilles et al. [2011], for any number $u \geq 3$. This concept class is shown in Table 5 for $u=3$. It is defined over $2^{u}+u$ instances $x_{1}, \ldots, x_{2^{u}+u}$. The set $\left\{x_{2^{u}+1}, \ldots, x_{2^{u}+u}\right\}$ of the last $u$ instances is shattered. Let $\alpha_{1}, \ldots, \alpha_{2^{u}}$ be the list of all possible assignments of labels to the last $u$ instances. For each such assignment $\alpha_{i}$, the concept class contains two concepts $C_{2 i-1}$ and $C_{2 i}$ realizing $\alpha_{i}$. The concept $C_{2 i-1}$ does not contain any of the first $2^{u}$ instances $x_{1}, \ldots, x_{2^{u}}$. The concept $C_{2 i}$ contains $x_{i}$, but none of the other instances in $\left\{x_{1}, \ldots, x_{2^{u}}\right\}$. See Table 5 for an illustration when $u=3$. Note that this concept class can be equivalently written in block matrix form as follows:

$$
\left[\begin{array}{ll}
I_{2^{u}} & P_{u} \\
0 & P_{u}
\end{array}\right]
$$

where $P_{u}$ represents the powerset over a set of $u$ instances and $I_{2^{u}}$ is the $2^{u} \times 2^{u}$ identity matrix.
It was proven by Zilles et al. [2011] that $\operatorname{STD}\left(\mathcal{C}_{u}^{\text {pair }}\right)=1$. We claim that $\operatorname{NCTD}\left(\mathcal{C}_{u}^{\text {pair }}\right)=\left\lceil\frac{u}{2}\right\rceil$. To see this, note that the subclass of concepts $C_{2 i-1}, 1 \leq i \leq 2^{u}$ is the powerset over the last $u$ instances, where all these concepts agree on the first $2^{u}$ instances. Thus, the NCTD of this subclass equals the NCTD of the powerset over $u$ instances, which is $\left\lceil\frac{u}{2}\right\rceil$ [Kirkpatrick et al., 2019]. Since NCTD is class-monotonic, we have $\operatorname{NCTD}\left(\mathcal{C}_{u}^{\text {pair }}\right) \geq\left\lceil\frac{u}{2}\right\rceil$. A teacher mapping $T$ witnessing $\operatorname{NCTD}\left(\mathcal{C}_{u}^{\text {pair }}\right) \leq\left\lceil\frac{u}{2}\right\rceil$ can be defined by (i) setting $T\left(C_{2 i}\right)=\left\{\left(x_{i}, 1\right)\right\}$ for $1 \leq i \leq 2^{u}$, and (ii) teaching the concepts $C_{2 i-1}, 1 \leq i \leq 2^{u}$, with a non-clashing teacher for the powerset over the last $u$ instances, as used by Kirkpatrick et al. [2019]. Clearly, $T$ is clash-free.

For $n \in \mathbb{N}$ and $u=2 n$, thus $\operatorname{STD}\left(\mathcal{C}_{u}^{\text {pair }}\right)=\operatorname{STD}_{\min }\left(\mathcal{C}_{u}^{\text {pair }}\right)=1$ and $\operatorname{NCTD}\left(\mathcal{C}_{u}^{\text {pair }}\right)=n$.
(ii) Consider the powerset $\mathcal{P}_{n}$ on $n$ instances. The fact that $\operatorname{NCTD}(\mathcal{C})=\frac{n}{2}$ was shown by Kirkpatrick et al. [2019]. It is obvious that $\mathrm{STD}_{\min }\left(\mathcal{P}_{n}\right)=n$ : Every sample set for a concept $C \in \mathcal{P}_{n}$ that omits one instance from $X$ is also a sample set for some concept $C^{\prime} \neq C, C^{\prime} \in \mathcal{P}_{n}$. Thus any subset teaching sequence for $\mathcal{P}_{n}$ satisfies $T_{k}=T_{0}$ for all $k \in \mathbb{N}$.

## E Details for Section 6

## E. 1 Proof Details for Theorem 20

To complete the proof of Theorem 20, we show that $\mathrm{STD}_{\min }$ is not unambiguous on Warmuth's class $\mathcal{C}_{W}$ which was defined by Doliwa et al. [2014] after communication with M. Warmuth. $\mathcal{C}_{W}$ is a concept class of 10 concepts over 5 instances, see Table 6. We know that $\operatorname{VCD}\left(\mathcal{C}_{W}\right)=$ $\operatorname{VCD}_{\text {min }}\left(\mathcal{C}_{W}\right)=2$, while $\operatorname{RTD}\left(\mathcal{C}_{W}\right)=\operatorname{STD}\left(\mathcal{C}_{W}\right)=3$. It turns out that $\operatorname{STD}_{\min }\left(\mathcal{C}_{W}\right) \leq 2$, as witnessed by the subset teaching sequence that is highlighted in Table6. However, there is a second $\mathrm{STD}_{\text {min }}$-teacher for $\mathcal{C}_{W}$ that has exactly the same range as the one resulting from the subset teaching sequence in Table 6- see Table 7. A comparison of Tables 6 and 7 shows that $T_{2}$ and $T_{2}^{\prime}$ swap the teaching sets for $C_{2 i-1}$ and $C_{2 i}$, for all $i \in\{1, \ldots, 5\}$.

## E. 2 Redundant Instances Can Cause Extreme Forms of Ambiguity

The ambiguity of $\mathrm{STD}_{\text {min }}$ can take extreme forms for artificially created concept classes that have many redundant instances. An instance $x \in X$ is redundant for $\mathcal{C}$ if $X \backslash\{x\}$ preserves $\mathcal{C}$.

Table 6: The concept class $\mathcal{C}_{W}$. A subset teaching sequence can be chosen by defining $T_{1}\left(C_{2 i}\right)$ to consist of the only three positive examples for $C_{2 i}$, and $T_{1}\left(C_{2 i-1}\right)$ to consist of the only three negative examples for $C_{2 i-1}$, where $1 \leq i \leq 5$. In $T_{2}$, these sets can easily be reduced to sets of size 2. Asterisks denote instances not occurring in the chosen teaching sets.

Example 1 For arbitrary $n \in \mathbb{N}$, consider a concept class for which VCD is $n$, while $\mathrm{STD}_{\text {min }}$ equals 1, with a large number of redundant instances. Such a class can be constructed over a domain $X$ that has $n 2^{n}$ instances and is partitioned into $2^{n}$ sets $X_{1}, \ldots, X_{2^{n}}$, each of size $n$. The concept class consists of $2^{n}$ concepts, chosen so that they shatter each set $X_{i}, 1 \leq i \leq 2^{n}$. See Table 8 for an illustration when $n=2$.
To see that $\mathrm{STD}_{\min }$ equals 1 , let $C_{1}, \ldots, C_{2^{n}}$ be an enumeration of all concepts in this concept class. It suffices to pick a teaching sequence as follows. We define $T_{1}\left(C_{i}\right)=\left\{\left(x, C_{i}(x)\right) \mid x \in X_{i}\right\}$, that means, we pick the instances in the ith set $X_{i}$ to represent the ith concept. Now $T_{2}\left(C_{i}\right)$ can consist of any single example from $T_{1}\left(C_{i}\right)$, since $T_{1}\left(C_{i}\right) \cap T_{1}\left(C_{j}\right)=\emptyset$ for all $j \neq i$.
Obviously, by reordering concepts, we obtain different $\mathrm{STD}_{\min }$-teachers that have the same range; in particular, they witness a very high degree of ambiguity, as will be formalized in Observation 1 .

Example 1 can be generalized to the following observation.
Observation 1 Let $\mathcal{C}$ be any concept class over a domain $X$. Suppose $X$ can be partitioned into a family $\left(X_{C}\right)_{C \in \mathcal{C}}$ of subsets such that $X_{C}$ preserves $\mathcal{C}$, for every $C \in \mathcal{C}$. Then $\mathrm{STD}_{\min }(\mathcal{C})=1$ and there are at least $|\mathcal{C}|$ ! pairwise distinct $\mathrm{STD}_{\min }$-teachers for $\mathcal{C}$ with the same range on $\mathcal{C}$. In particular, every permutation $\sigma$ of $\mathcal{C}$ yields an $\mathrm{STD}_{\min }$-teacher that maps a concept $C$ to the singleton sample set $\left\{\left(x_{\sigma(C)}, C\left(x_{\sigma(C)}\right)\right)\right\}$, where $x_{\sigma(C)}$ is any instance in $X_{\sigma(C)}$.

| $T_{0} T_{1}^{\prime}=T_{0}$ | $T_{1}^{\prime}$ |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| concept | $x_{1}$ | $x_{2}$ | $x_{3}$ | $x_{4}$ | $x_{5}$ | $x_{1}$ | $x_{2}$ | $x_{3}$ | $x_{4}$ | $x_{5}$ | $x_{1}$ | $x_{2}$ | $x_{3}$ | $x_{4}$ | $x_{5}$ |
